Abstract

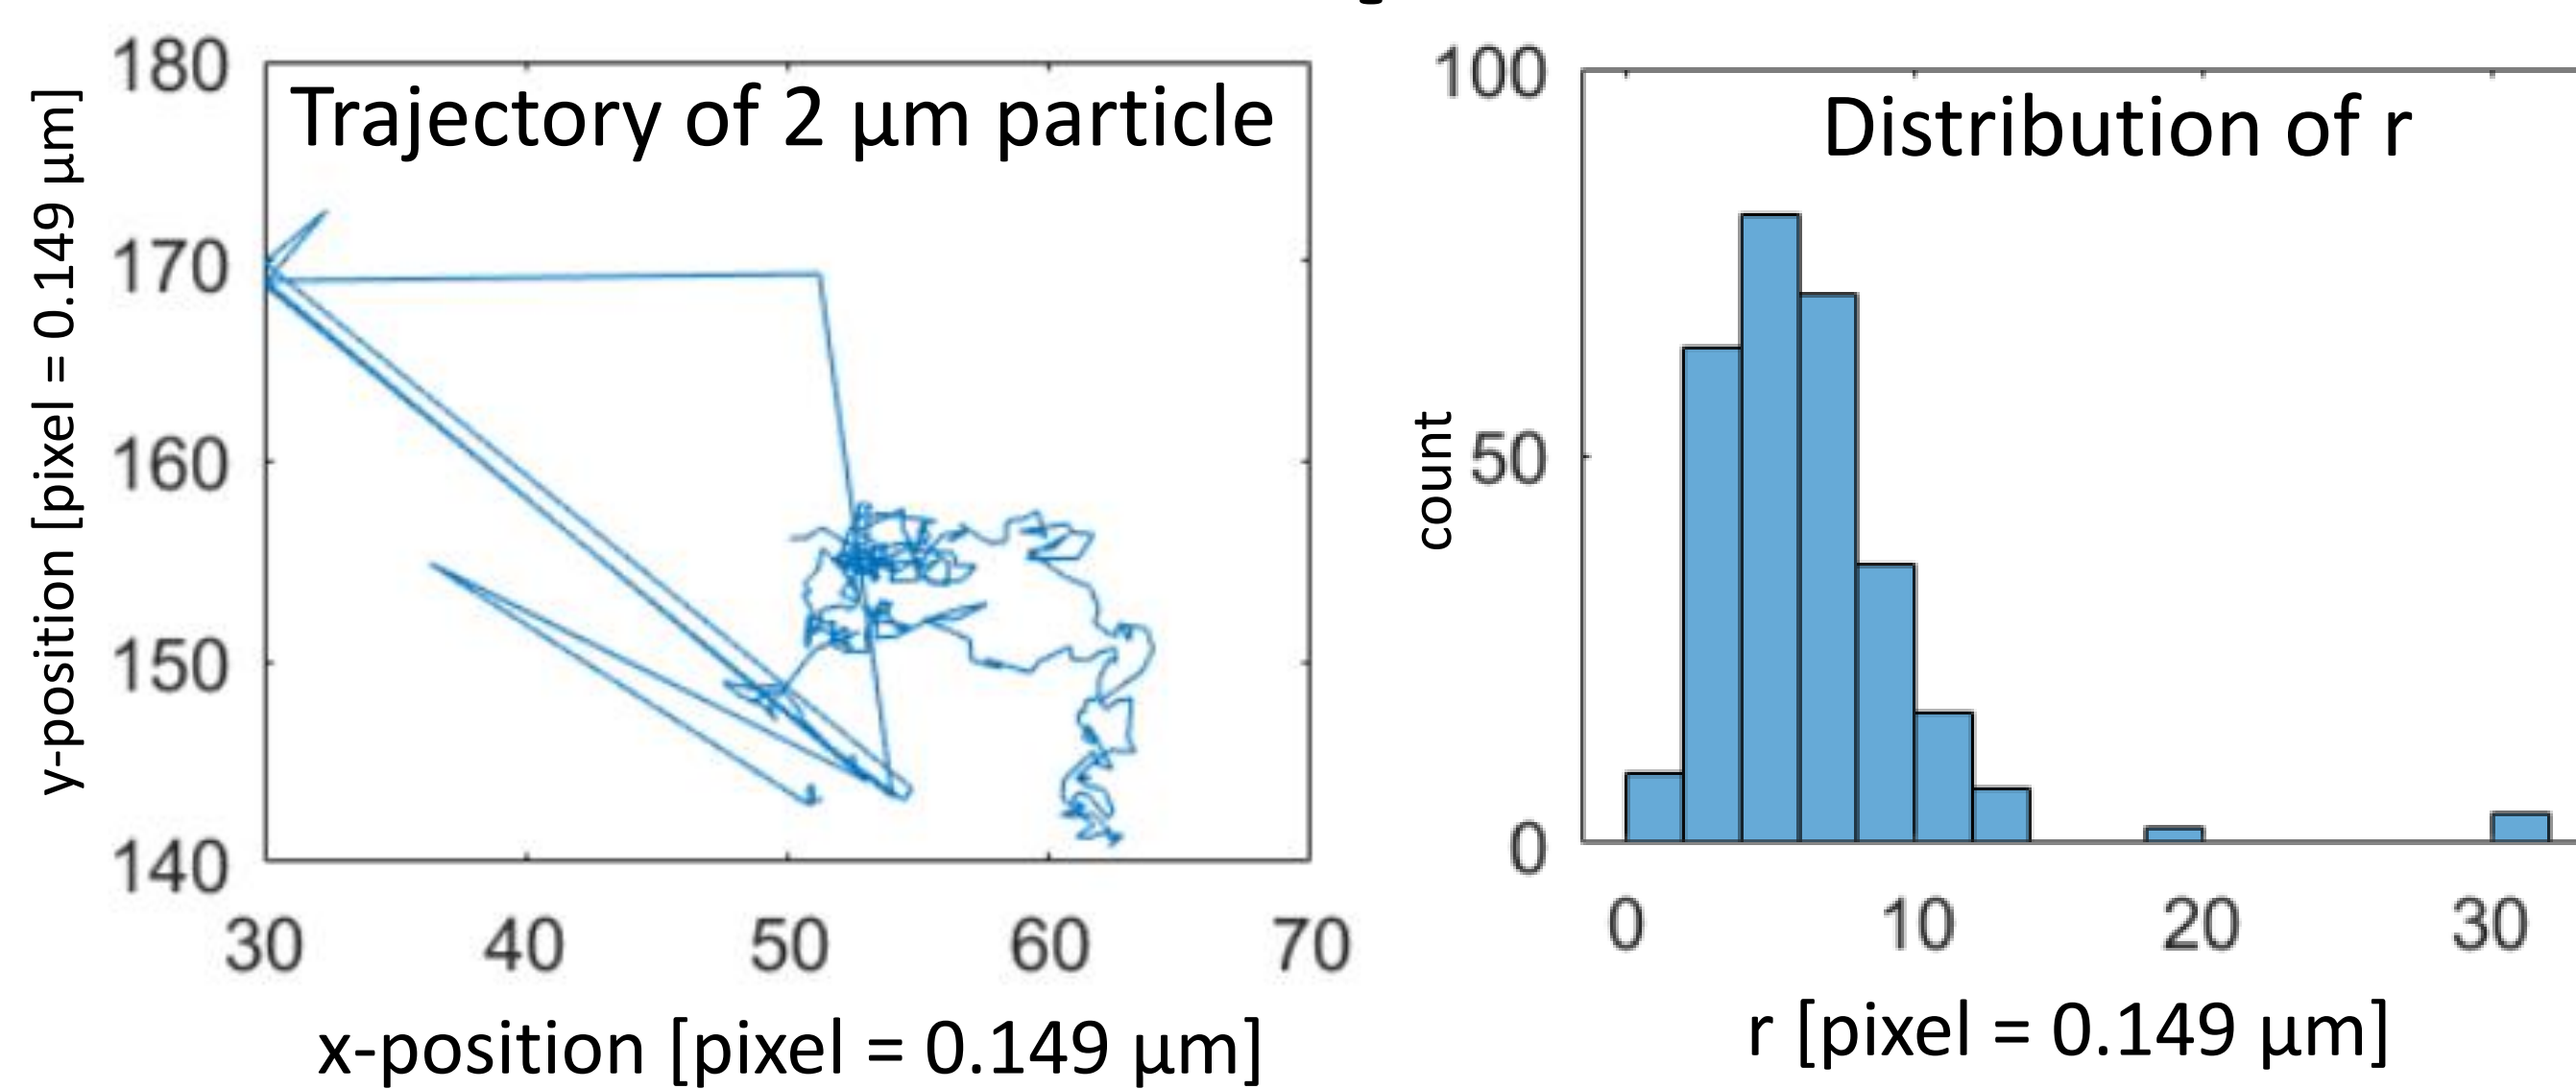

We constructed an optical tweezer by modifying a microscope and succeeded to trap some microparticles. We tried to develop a new method to measure the trap force constant of an optical tweezer by using overdamped motion formula and also found out some relations between trap force constant and diameter of the microsphere.

The schematic diagram of the equipment and the light path

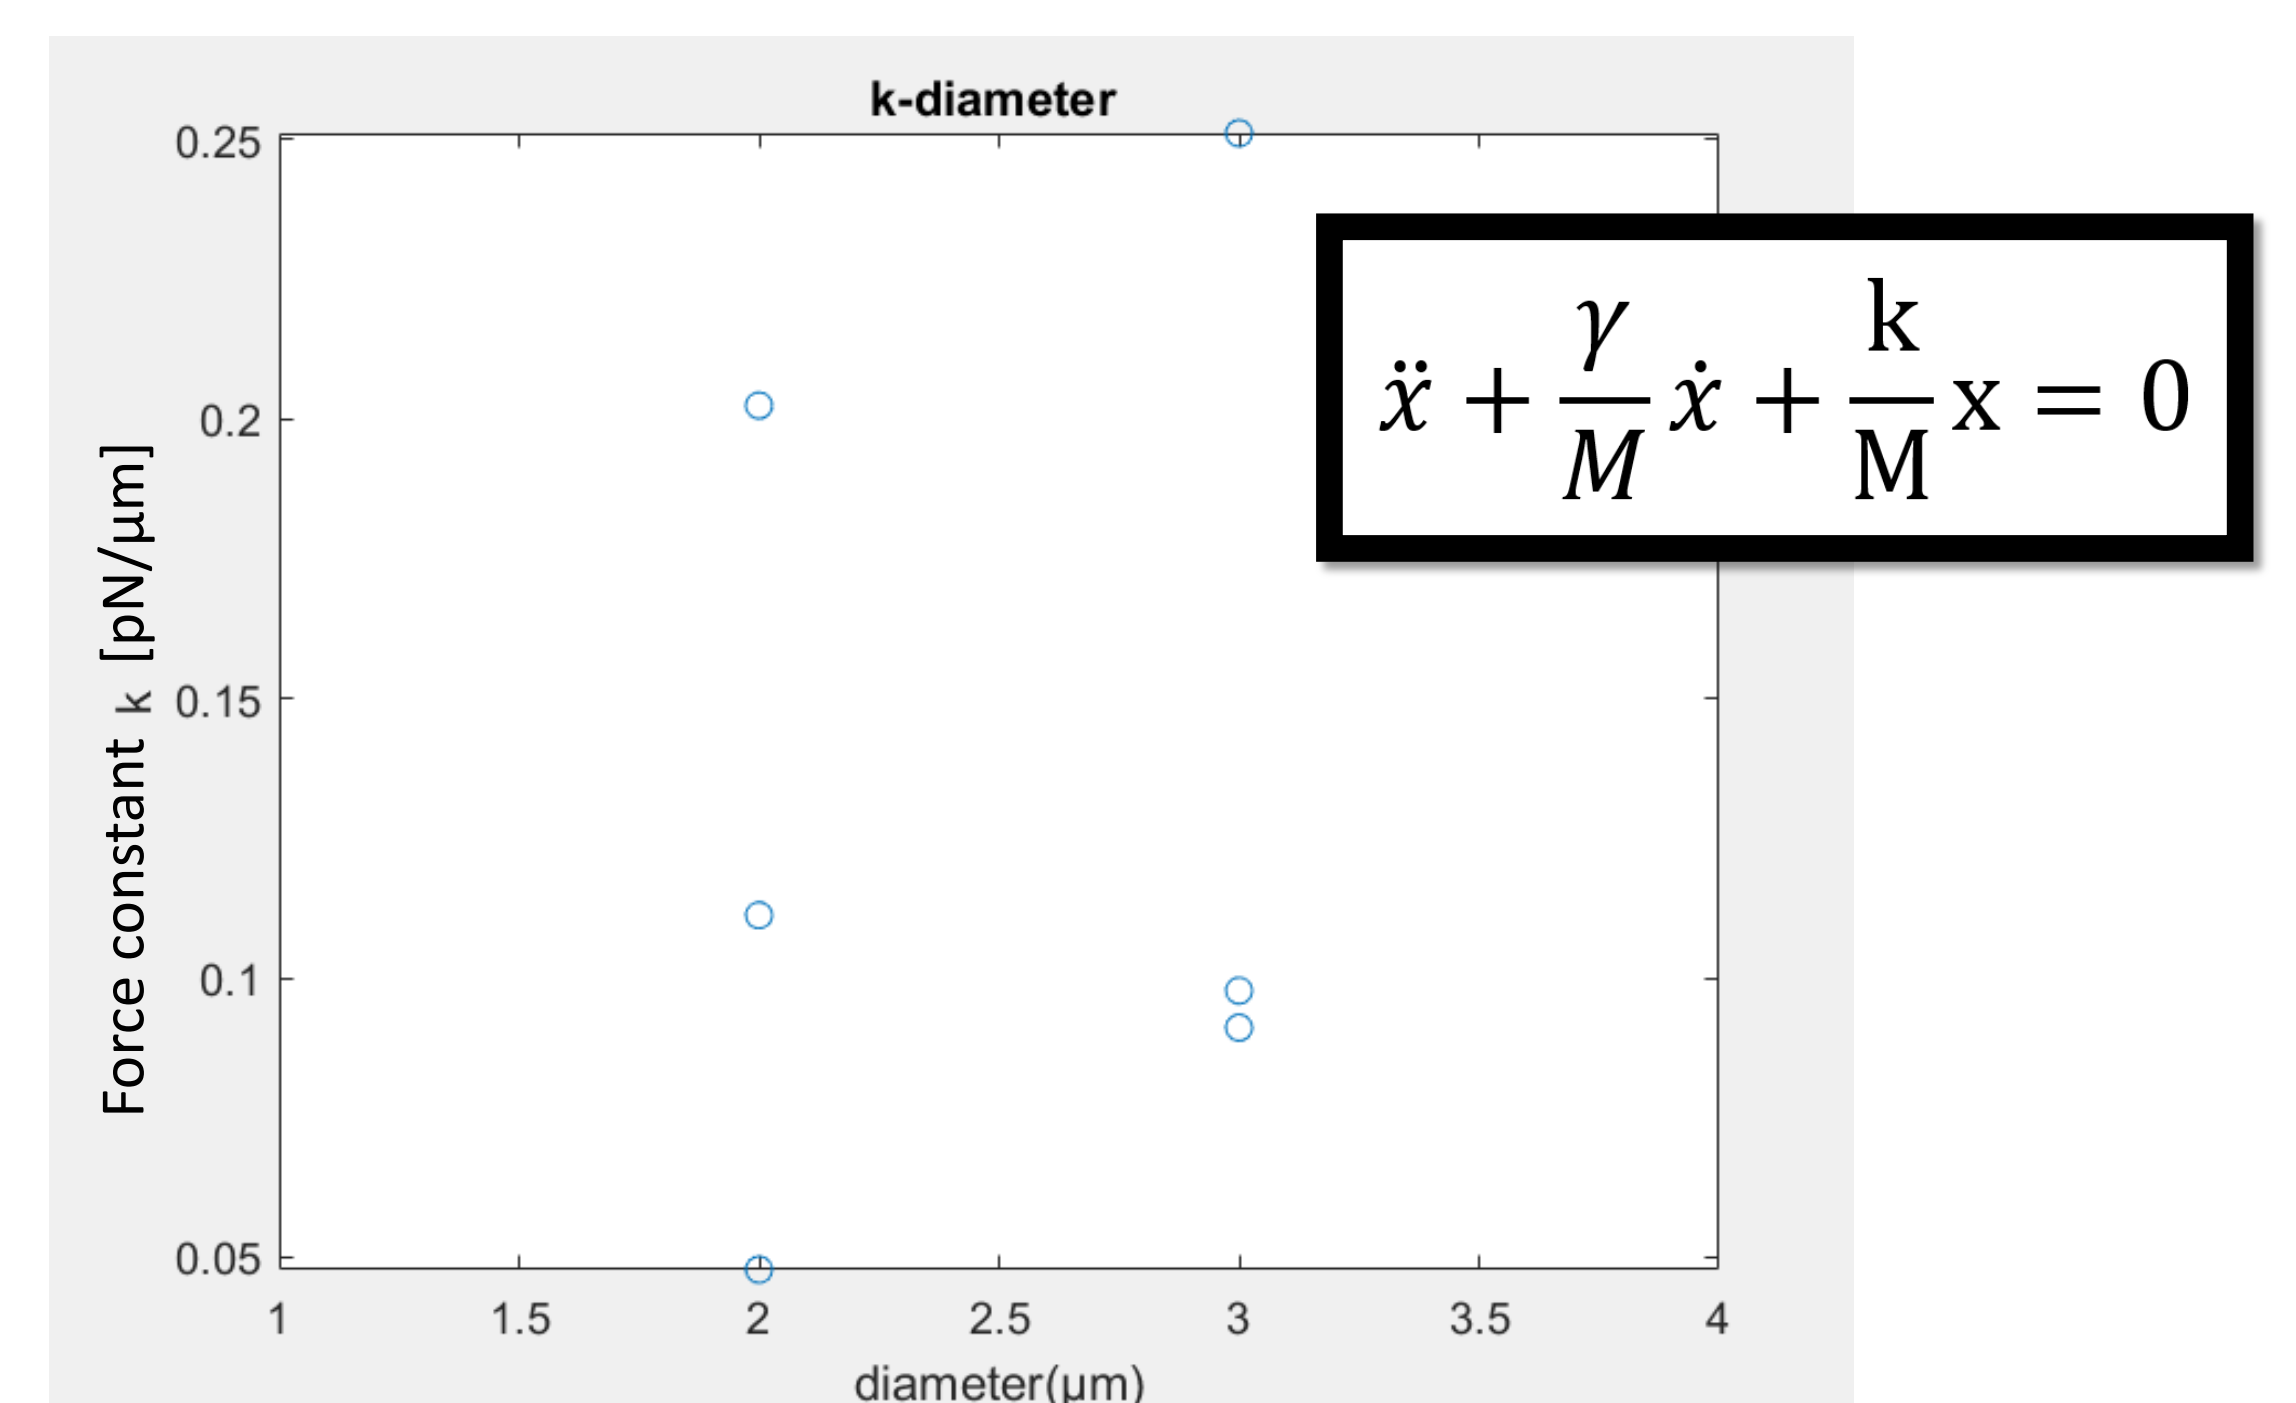

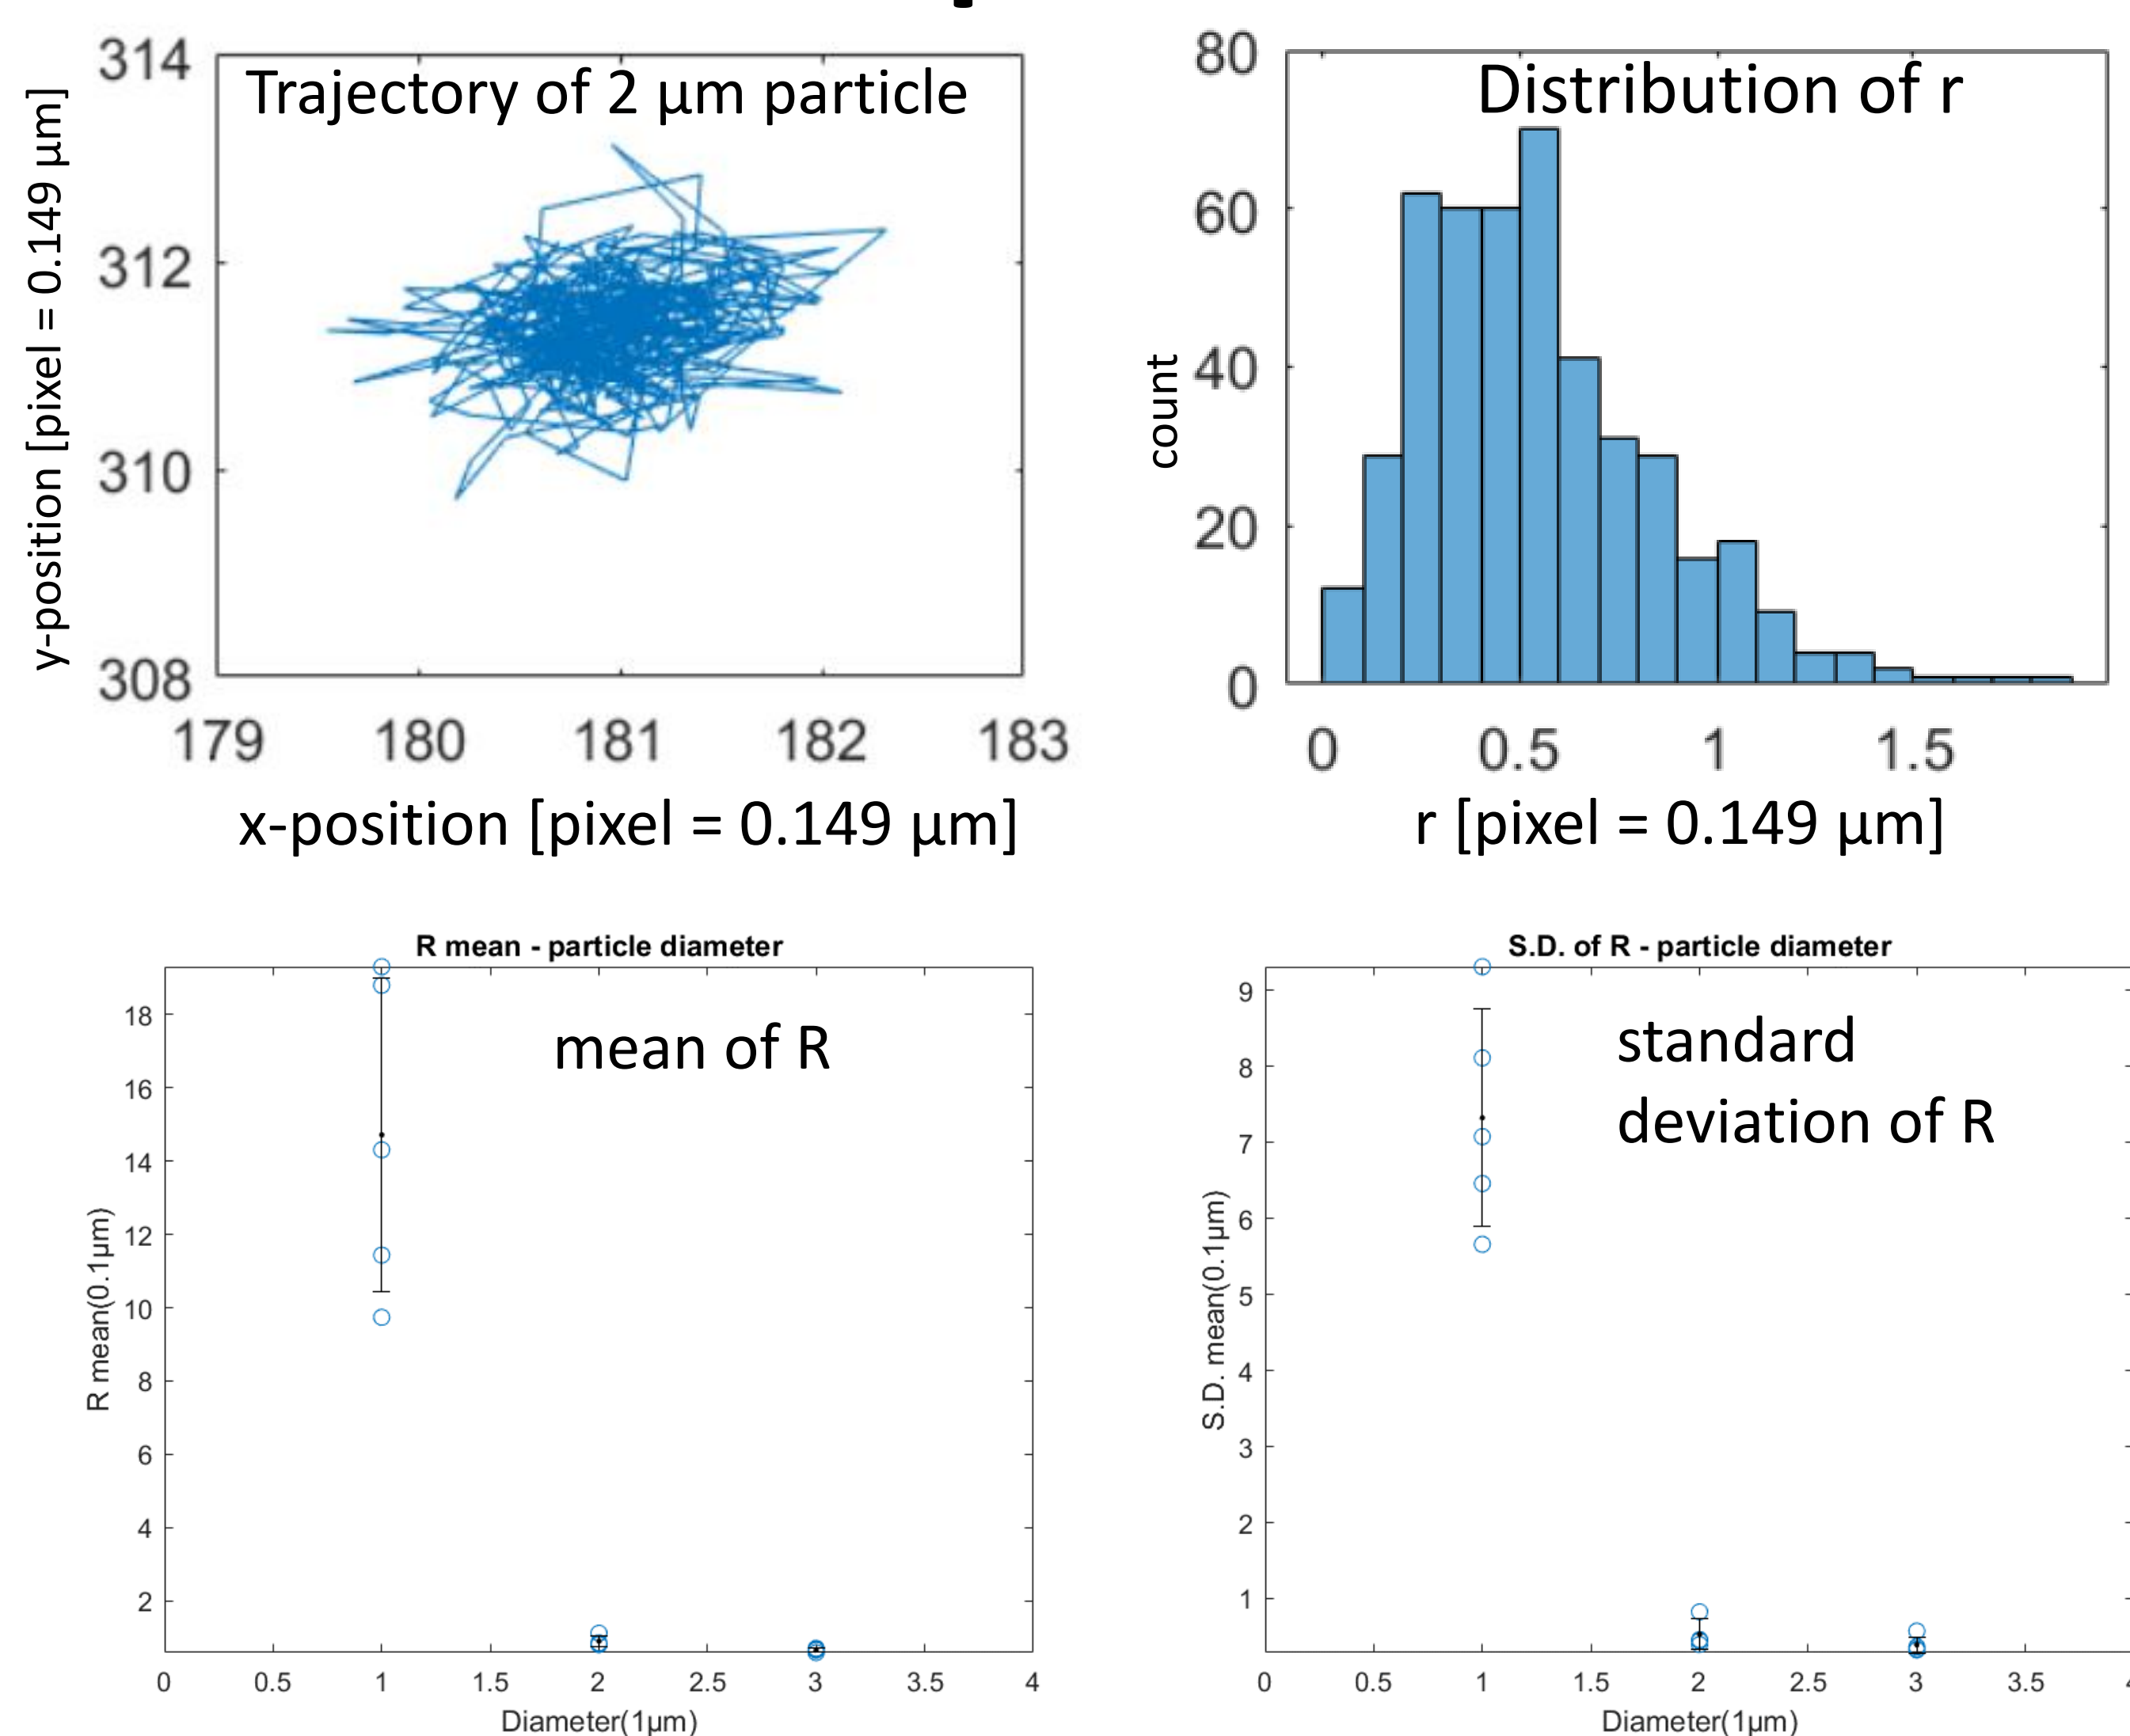

Without the optical tweezer

Stiffness

With the optical tweezer

Conclusion

1. We found how to construct an optical tweezer by using a He-Ne laser generator and modifying a microscope.
2. The greater the diameter of a trapped microsphere is, the greater the trap force is.
3. It is possible to measure and calculate the force constant by using overdamped formula. We have to do more experiments to check its accuracy.
